

Problem Set 2

May 3, 2012

Due: Fri, May 18, *before 5.00pm*
Location: **Dropbox A** (in alcove behind Econ 100)
Instructor: Marc-Andreas Muendler
E-mail: muendler@ucsd.edu

1 The Empirics of Purchasing Power Parity and Exchange Rates

Examine the MXN/USD (peso-dollar) nominal exchange rate and the ratio of the Mexican and the US CPI for the period from February 1993 to December 2006. What do you observe? Does absolute or relative PPP seem to hold in the long term? If not, what might be reasons for failure? Repeat the exercise for the MXN/USD black-market exchange rate for the period from February 1993 to December 1998.

You may choose not to print the graphs. In that case, draw the stylized figures for your answer.

Data. Visit <https://www.globalfinancialdata.com/> and display the nominal MXN/USD exchange rate (symbol: XRNMEXM), the MXN/USD black-market exchange rate (symbol: USDMXNB), the consumer price index in Mexico (symbol: CPMEXM), and the consumer price in the US (symbol: CPUSAM). To view a series, enter the according symbol in the “GFD AutoSearch” box in the upper left-hand corner. You may want to download the series into four separate spreadsheets, then copy and paste the MXN/USD exchange rate and the two CPI series into one spreadsheet, and copy and paste the MXN/USD black-market exchange rate and the two CPI series into another spreadsheet. To plot the ratio between the Mexican and the US CPI, you can divide the Mexican CPI series by the US series directly (e.g. if the first Mexican CPI observation is in cell b2 in Excel and the first US CPI observation in cell c2, you could use the formula “=B2/C2” for the current cell on line 2) and then plot the resulting series by highlighting it and clicking the “Chart Wizard” button from the Excel toolbar. Select a line chart and then click the “Next” button. In the following window, select the “Series” tab and use the series of dates in the left column as the “Category (X) axis labels”.

2 The DD-AA Model

Small open economies tend to spend a larger fraction of income on imports than large economies do. Their import volumes are also more responsive to changes

in their national income. Does this imply that the DD-curve in the Netherlands, a smaller and more open economy than the US, is flatter than the DD-curve in the US?

Hint: Your answer depends on what you assume regarding the current-account responsiveness to the real exchange rate in a small open economy. Use the “Keynesian cross” to derive your answer.

Would a temporary monetary expansion in the Netherlands have a stronger or weaker effect on output? Use an AA-DD diagram to substantiate your answer.

3 Import Tariffs and the Current Account

Take a commodity-trade perspective of the current account and suppose restrictions of import volumes do have an effect on values. The government imposes a tariff on all imports. Use the DD-AA model to analyze the effects this measure would have on the economy. Consider both *temporary* and *permanent* tariffs.

In question 1 of problem set 1, you were asked to take a purely financial view of the current account with savings and investment decisions dictated by world real interest rates. Under that point of view, your answer was different. Why?

4 Monetary and Fiscal Policy under Different Exchange Rate Regimes

Show the effects of a *temporary* and a *permanent* monetary contraction on the current account, interest rates and output under a floating exchange rate and under a fixed exchange rate. Do the two policies have different effects under a fixed exchange rate? Why or why not?

Show the effects of a *temporary* and a *permanent* fiscal expansion on the current account, interest rates and output under a floating exchange rate and under a fixed exchange rate. Do the two policies have different effects under a fixed exchange rate? Why or why not?

5 Macroeconomic Analysis and Intervention

Take the perspective of a South Korean resident. In particular, let E denote the KRW/USD (Won-US Dollar) exchange rate so that an elevated E means a depreciated Won. You observe the following simultaneous macroeconomic developments: A fall in Korean output, an appreciation of the KRW, and a fall in the Korean current account.

Which of the following *temporary* shocks is mostly likely to explain this macroeconomic pattern: A shock to consumer tastes for Korean goods, a shock to money demand, or a shock to investment? Use the DD-AA-XX model to explain your answer.

The Korean government wishes to restore output to its level before the shock, while retaining the current account balance as close as possible to its pre-shock level. Would you recommend monetary or fiscal intervention? What is the effect of your policy on the KRW exchange rate? Use the DD-AA-XX model to substantiate your answer.

6 Money Supply, Imperfect Asset Substitutability and the Nominal Exchange Rate

The Adjusted Uncovered Interest Condition can be expressed as

$$R = R^* + \frac{E^e - E}{E} + \rho,$$

where ρ is the risk premium of domestic bonds over foreign bonds. How does an increased supply of domestic bonds to the private sector affect the risk premium ρ ? Redraw the foreign exchange equilibrium diagram, showing the exchange rate and the expected currency returns, under the Adjusted Uncovered Interest Condition.

The Federal Reserve System increases aggregate money supply permanently, purchasing domestic bonds in the open market. Use diagrams showing the exchange rate, expected currency returns and money holdings to analyze the *short-term* and the *long-term* effects on the US interest rate, the US price level and the nominal exchange rate. Compare your answer to question 6 of problem set 1.

Hint: Effects on the risk premium are small in practice compared to the Fisher effect.
